An aerial photograph of a barrier island. A multi-lane road runs along the length of the island, separating the ocean on the left from an inlet on the right. The beach is wide and sandy, with some people visible. The inlet has a winding path through the island, and there are some buildings and vegetation on the right side. The sky is clear and blue.

Decadal Relationship Between Foredune and Beachface Volume Change at an Inlet-influenced Florida Barrier Island

Teagan Duenkel and Peter N. Adams, PhD

University of Florida

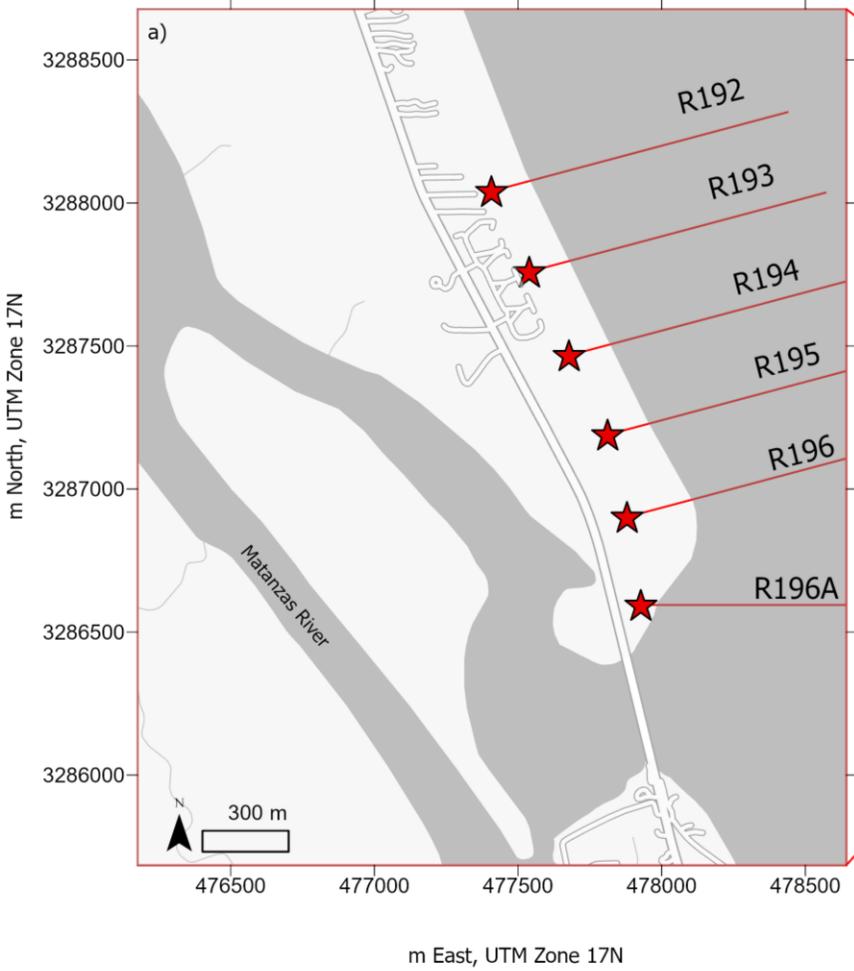

FSBPA Tech Conference, 2026

Motivation

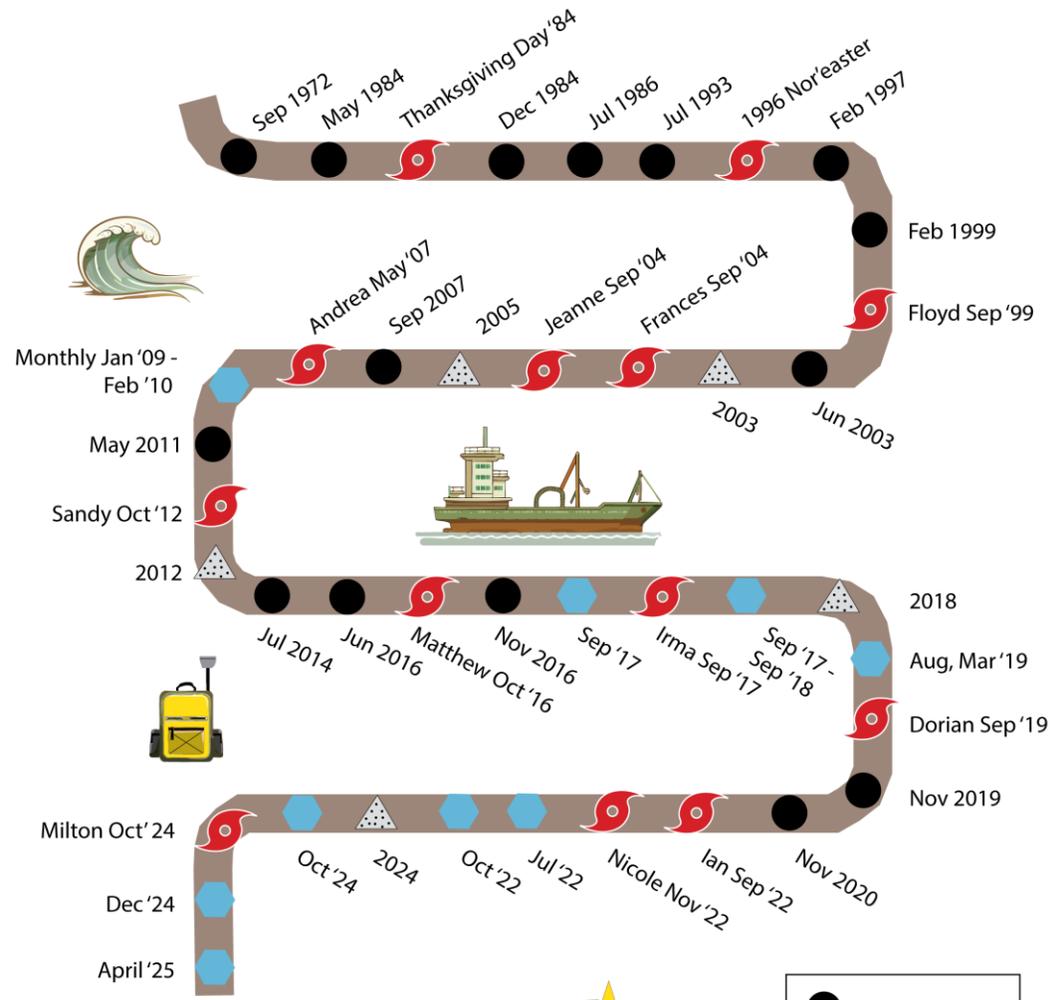

- Inlet-influence on adjacent beaches is widely recognized, but multi-decadal morphologic studies are still limited.
- Here we use 50 years of FDEP profiles and over a decade of UF RTK surveys at an unstructured inlet to better understand foredune-beachface coupling.

Event and Survey History of Matanzas Beach, FL

★ We are 11 mi north

Matanzas Beach, FL

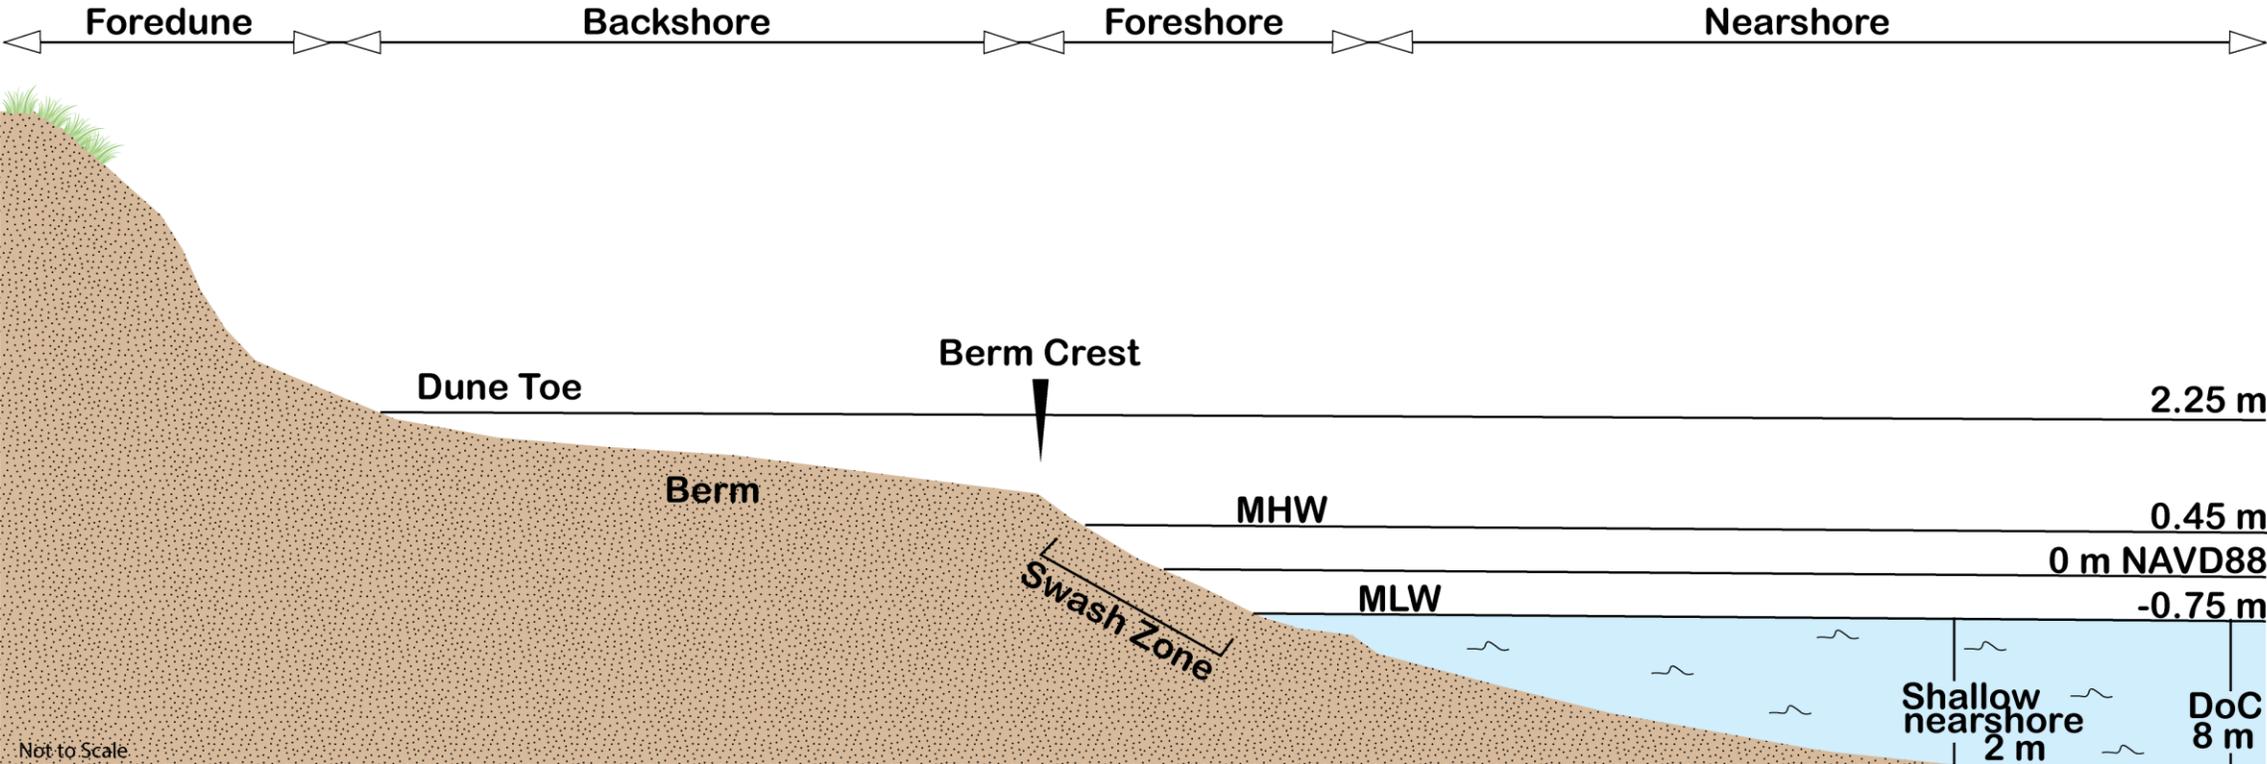

- FDEP Survey
- UF Survey
- Storm Event
- St. Augustine Nourishment

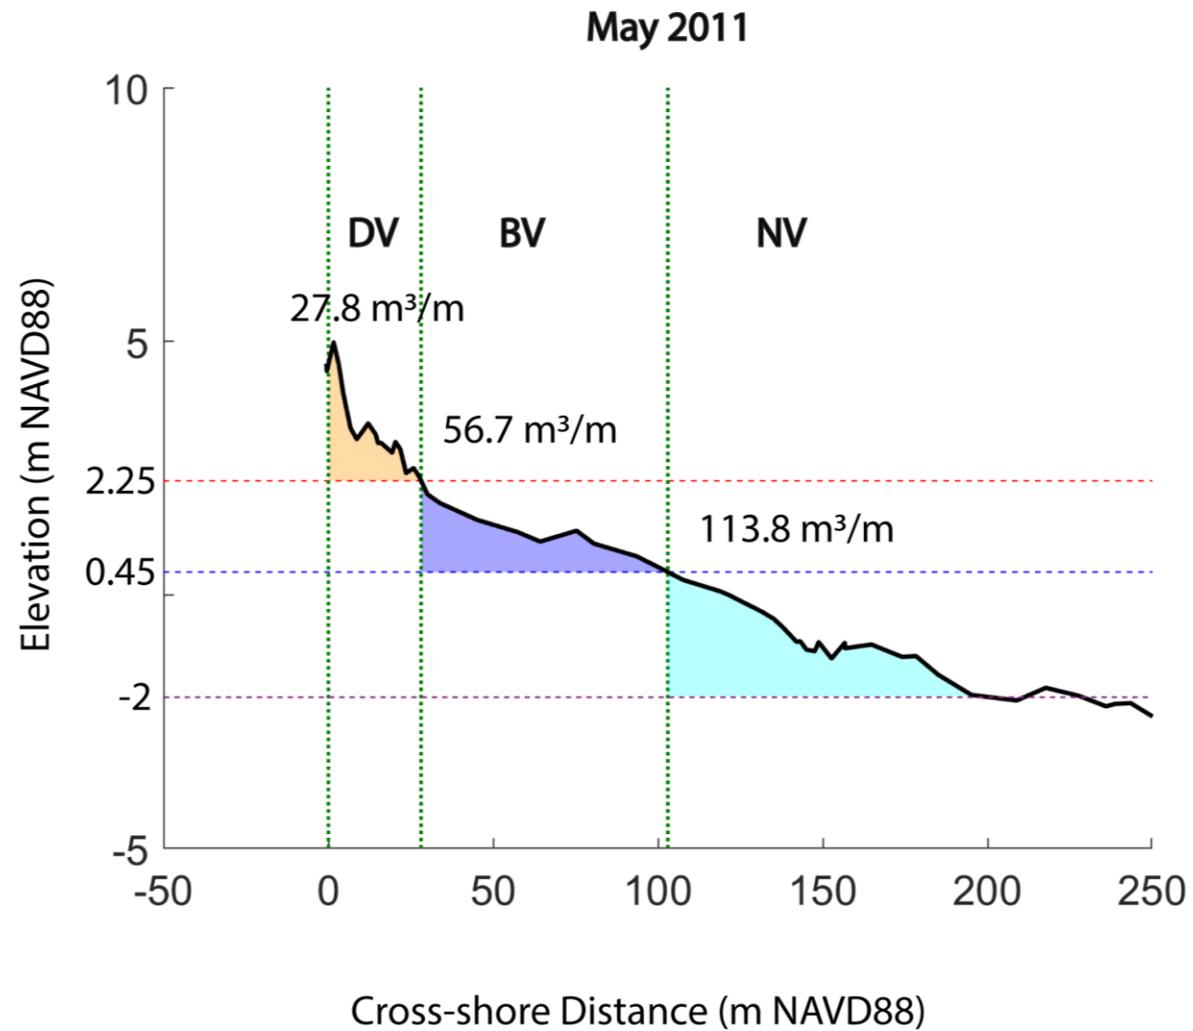

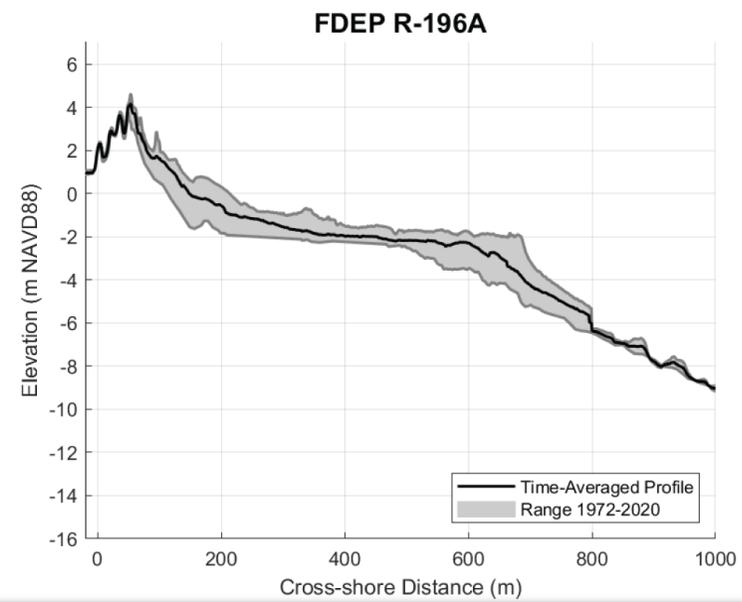

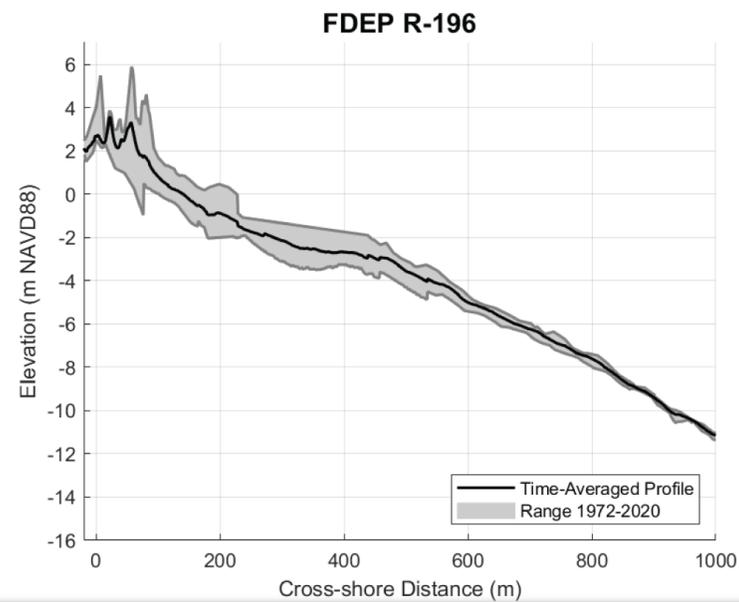

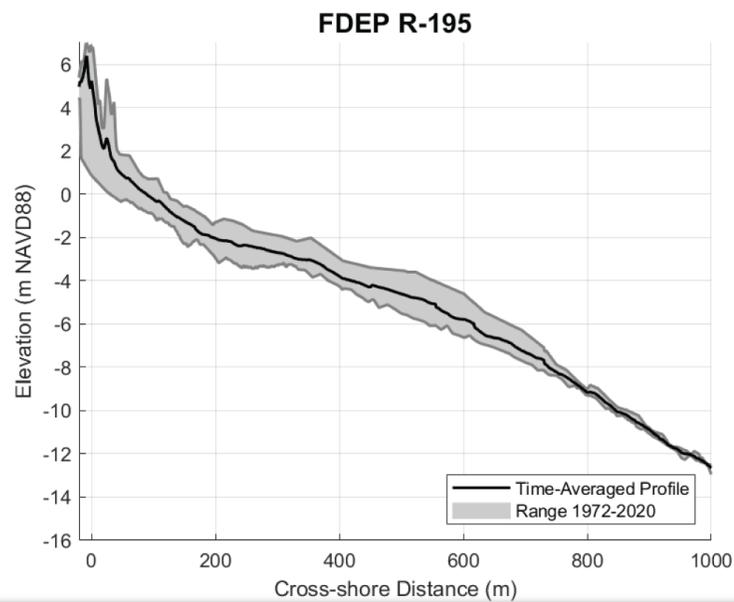

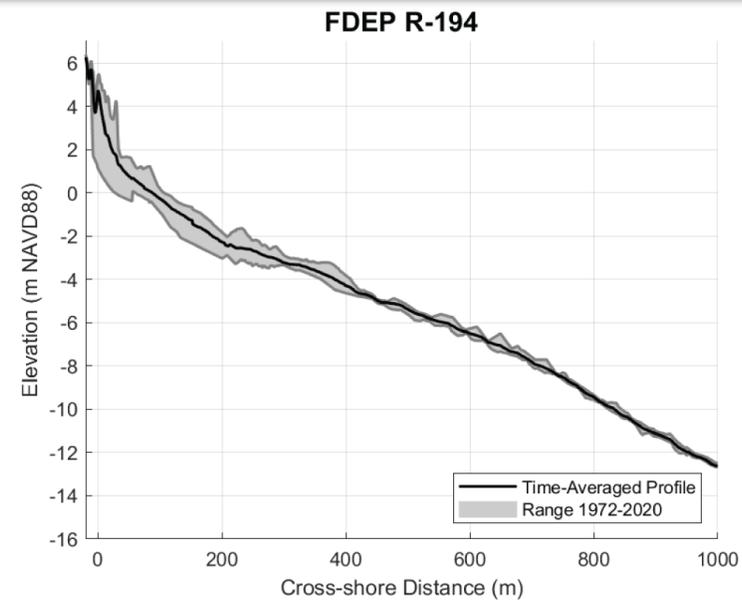

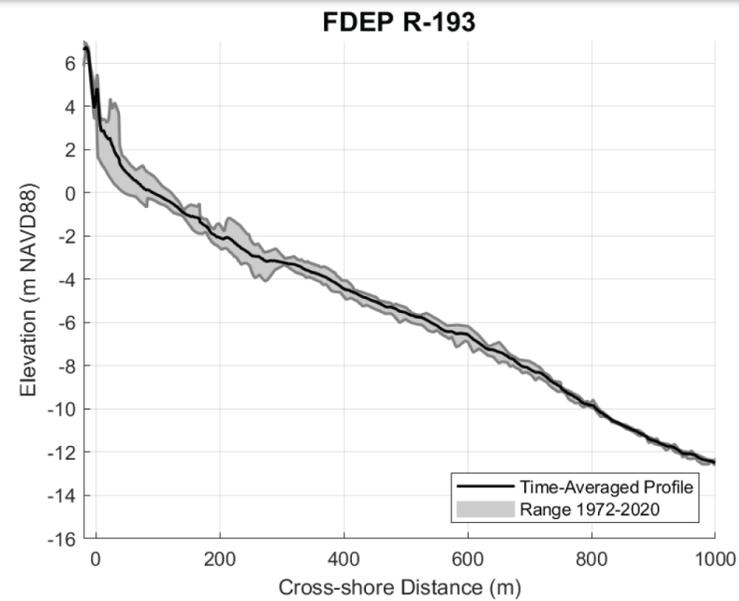

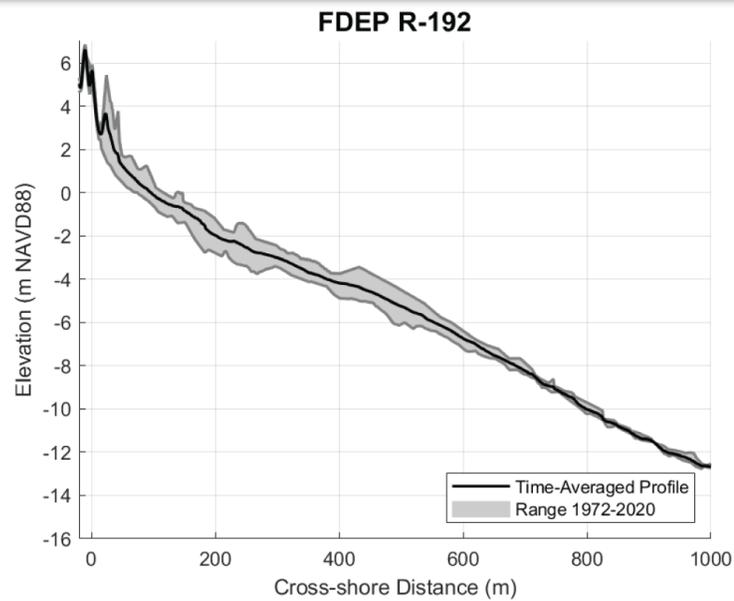

Vertical Datum: NAVD88 m
Dune Toe 2.25 m
MHW 0.45 m
Shallow nearshore/inner surf -2 m

**Matanzas Beach
Profile Schematic**

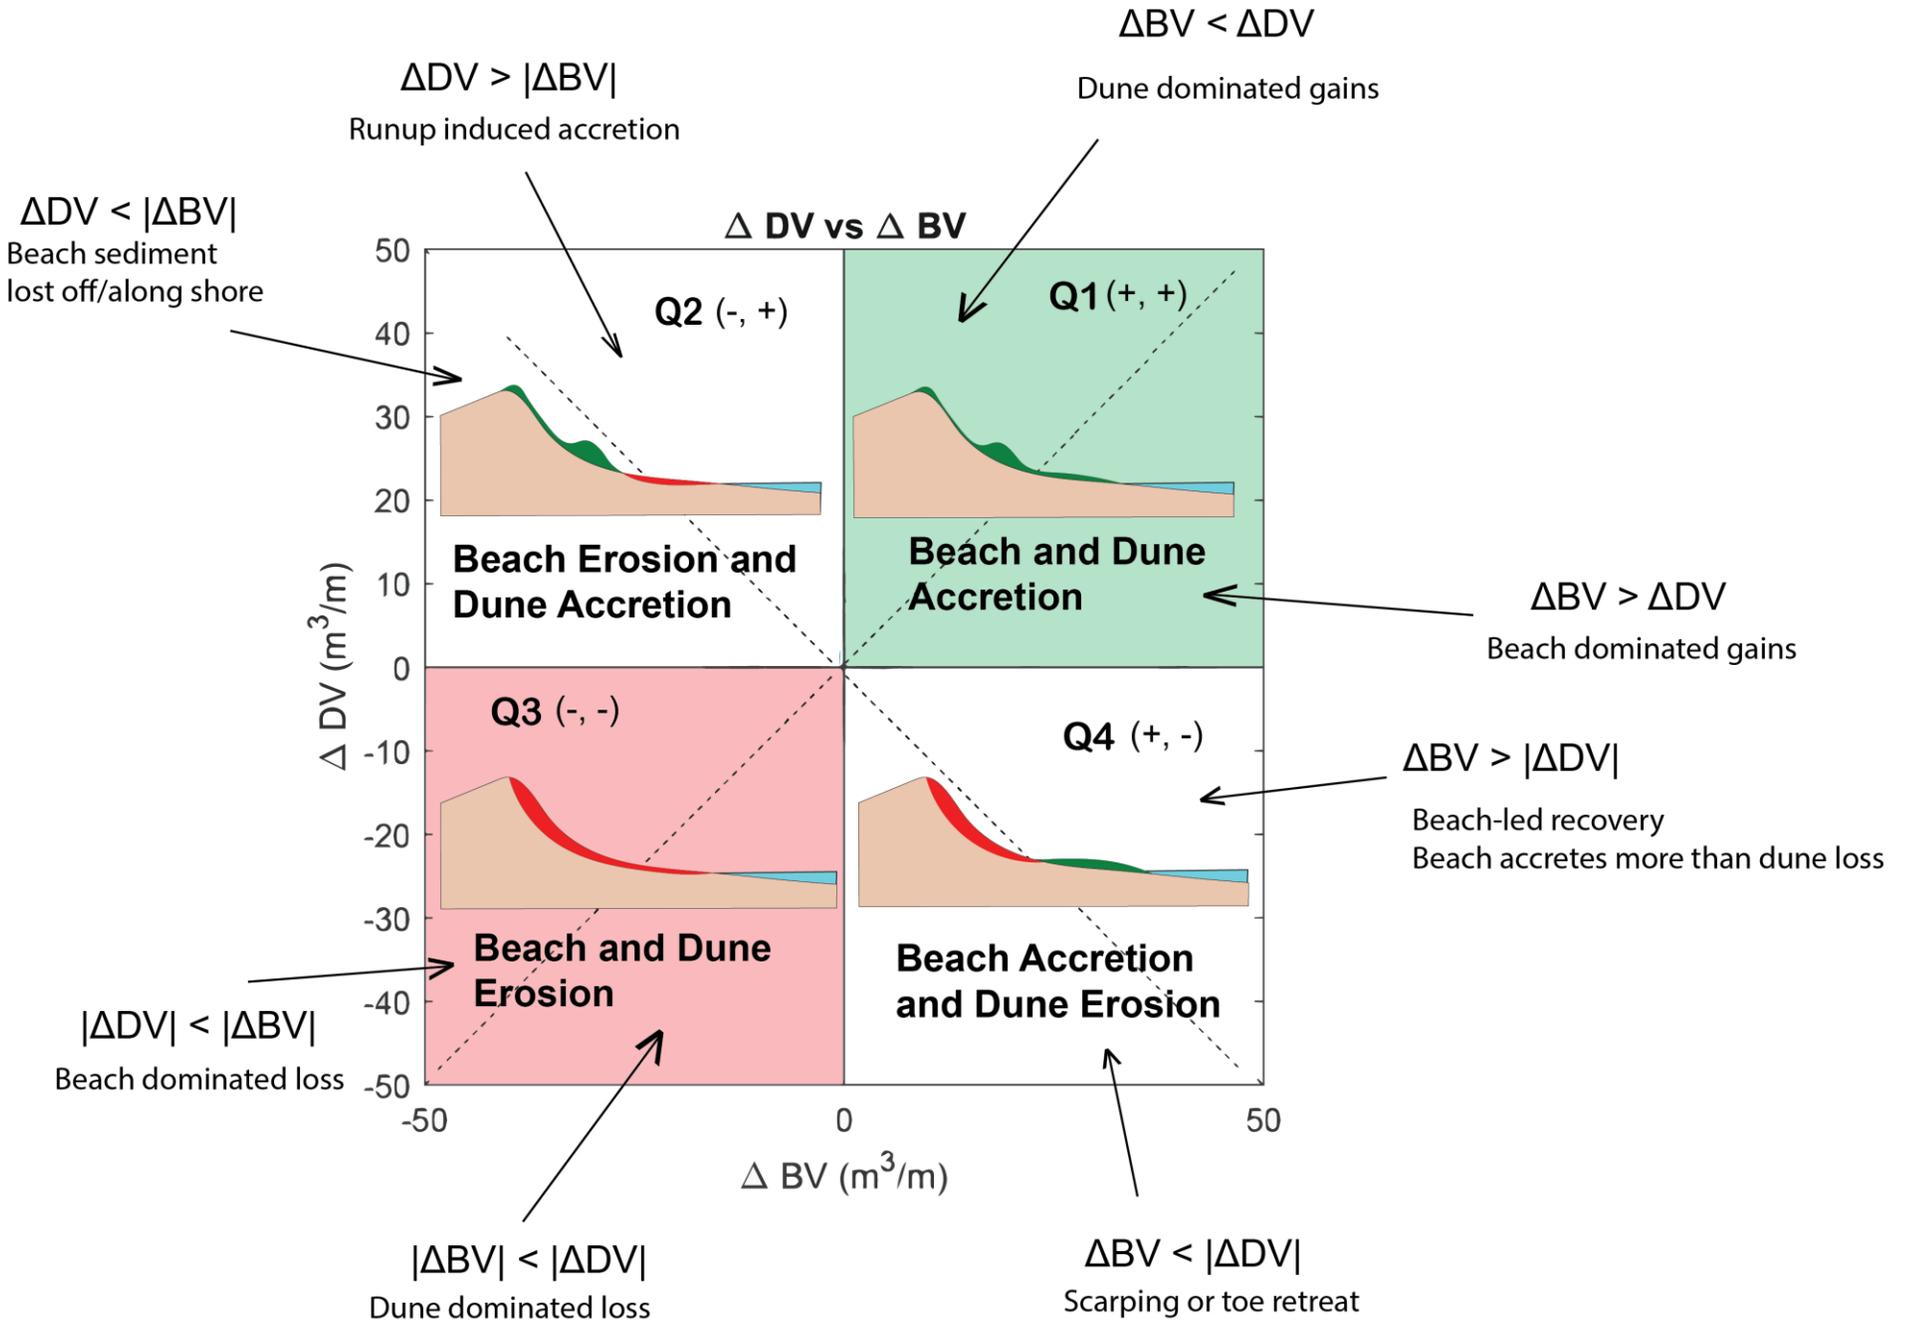

Cross-shore volumetric integration:

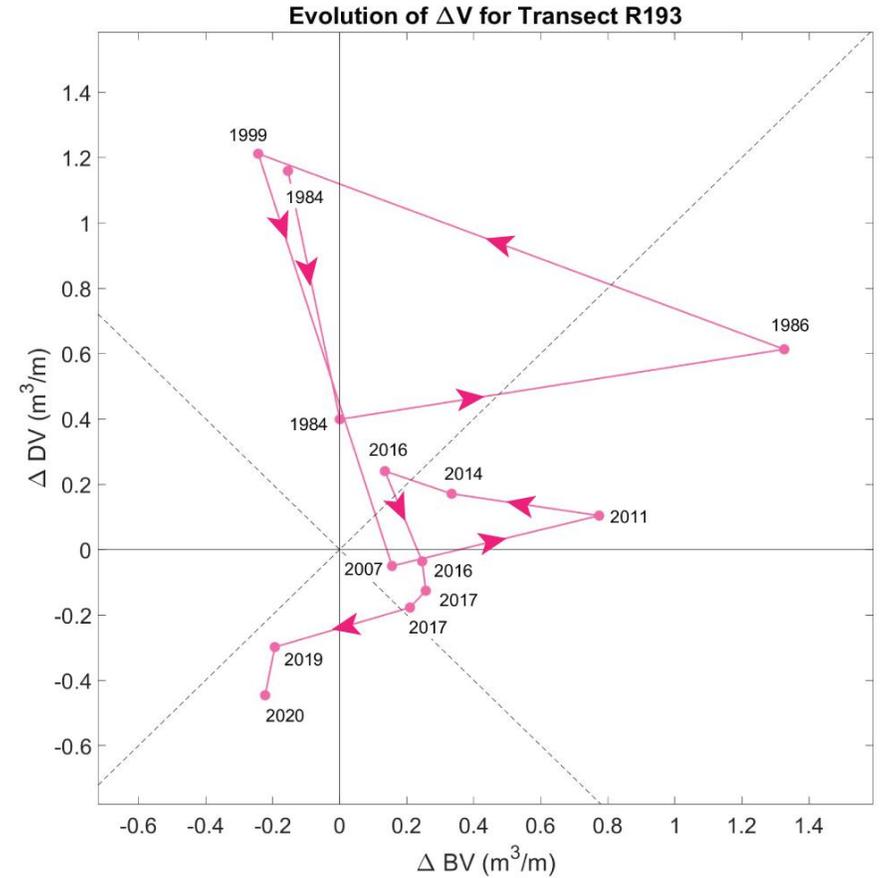

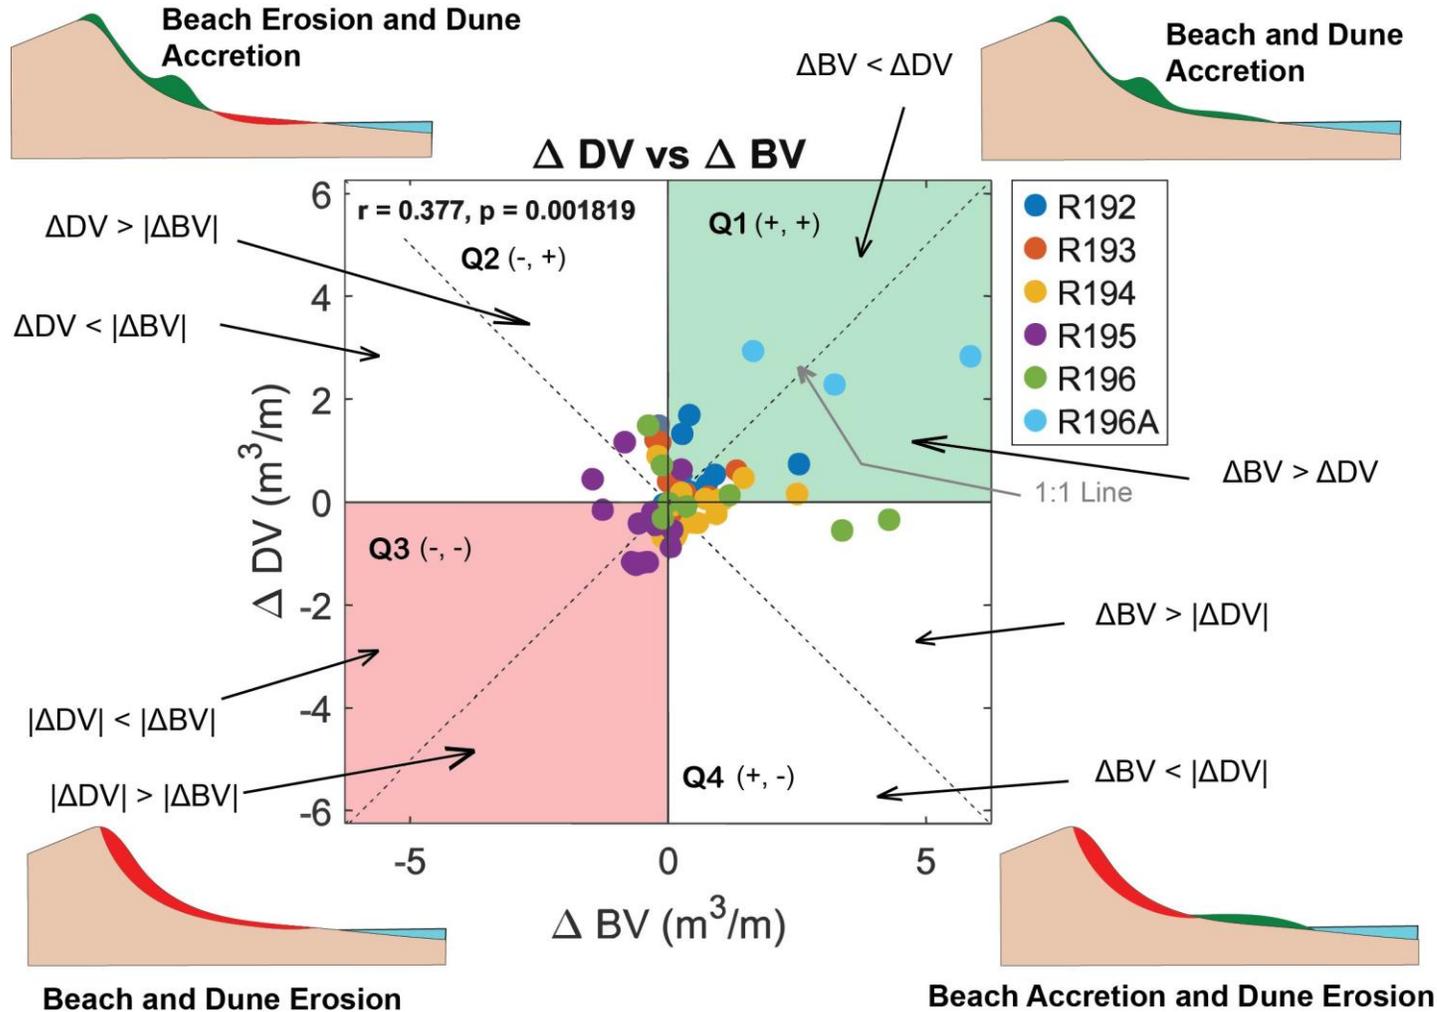

- Correlation of the **change in beach volume** to the **change in dune volume** normalized by time

- First, relative to Baseline survey
- Later, Sequential change

Baseline-referenced

Points = volume change relative to baseline survey volume

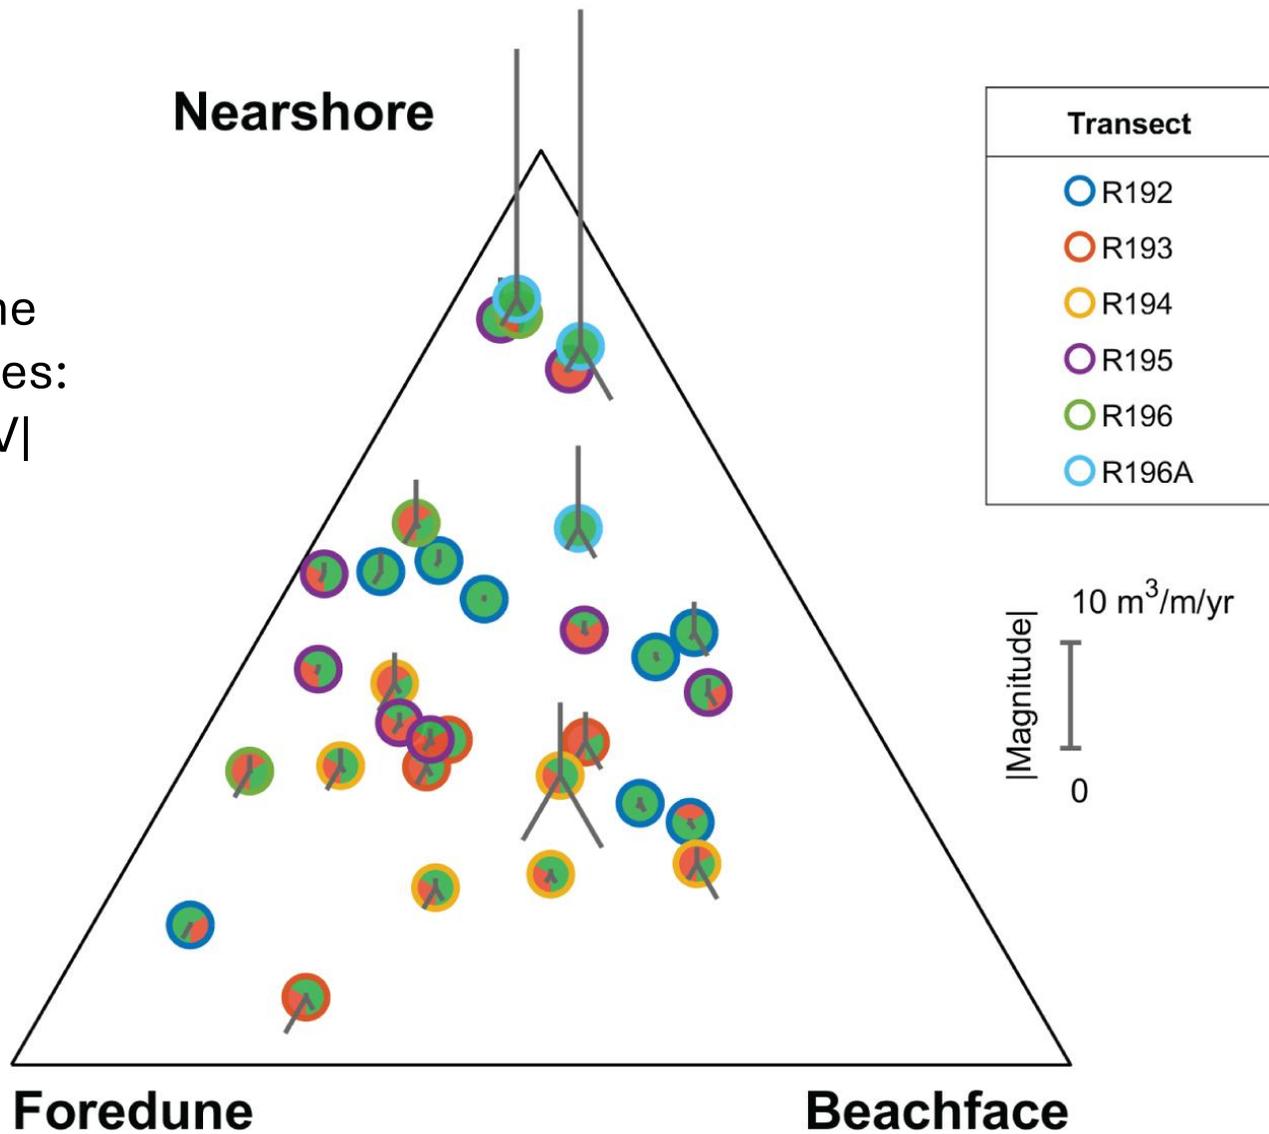

Fractions of total volume
change among three zones:

$$S = |\Delta DV| + |\Delta BV| + |\Delta NV|$$

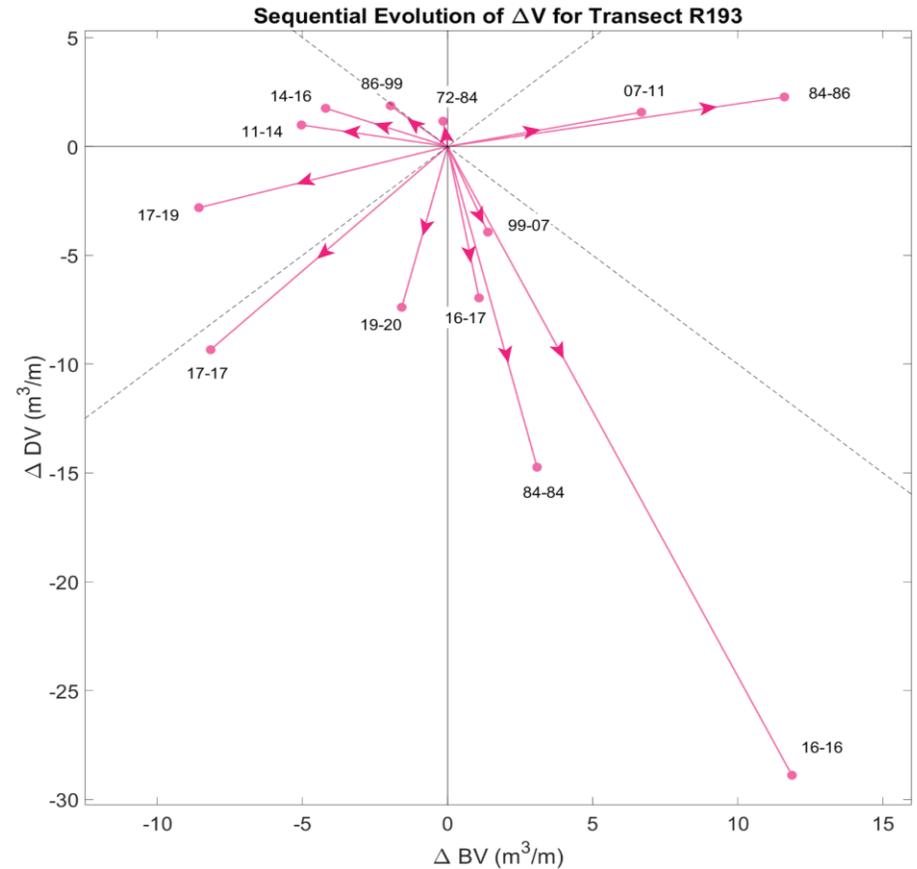

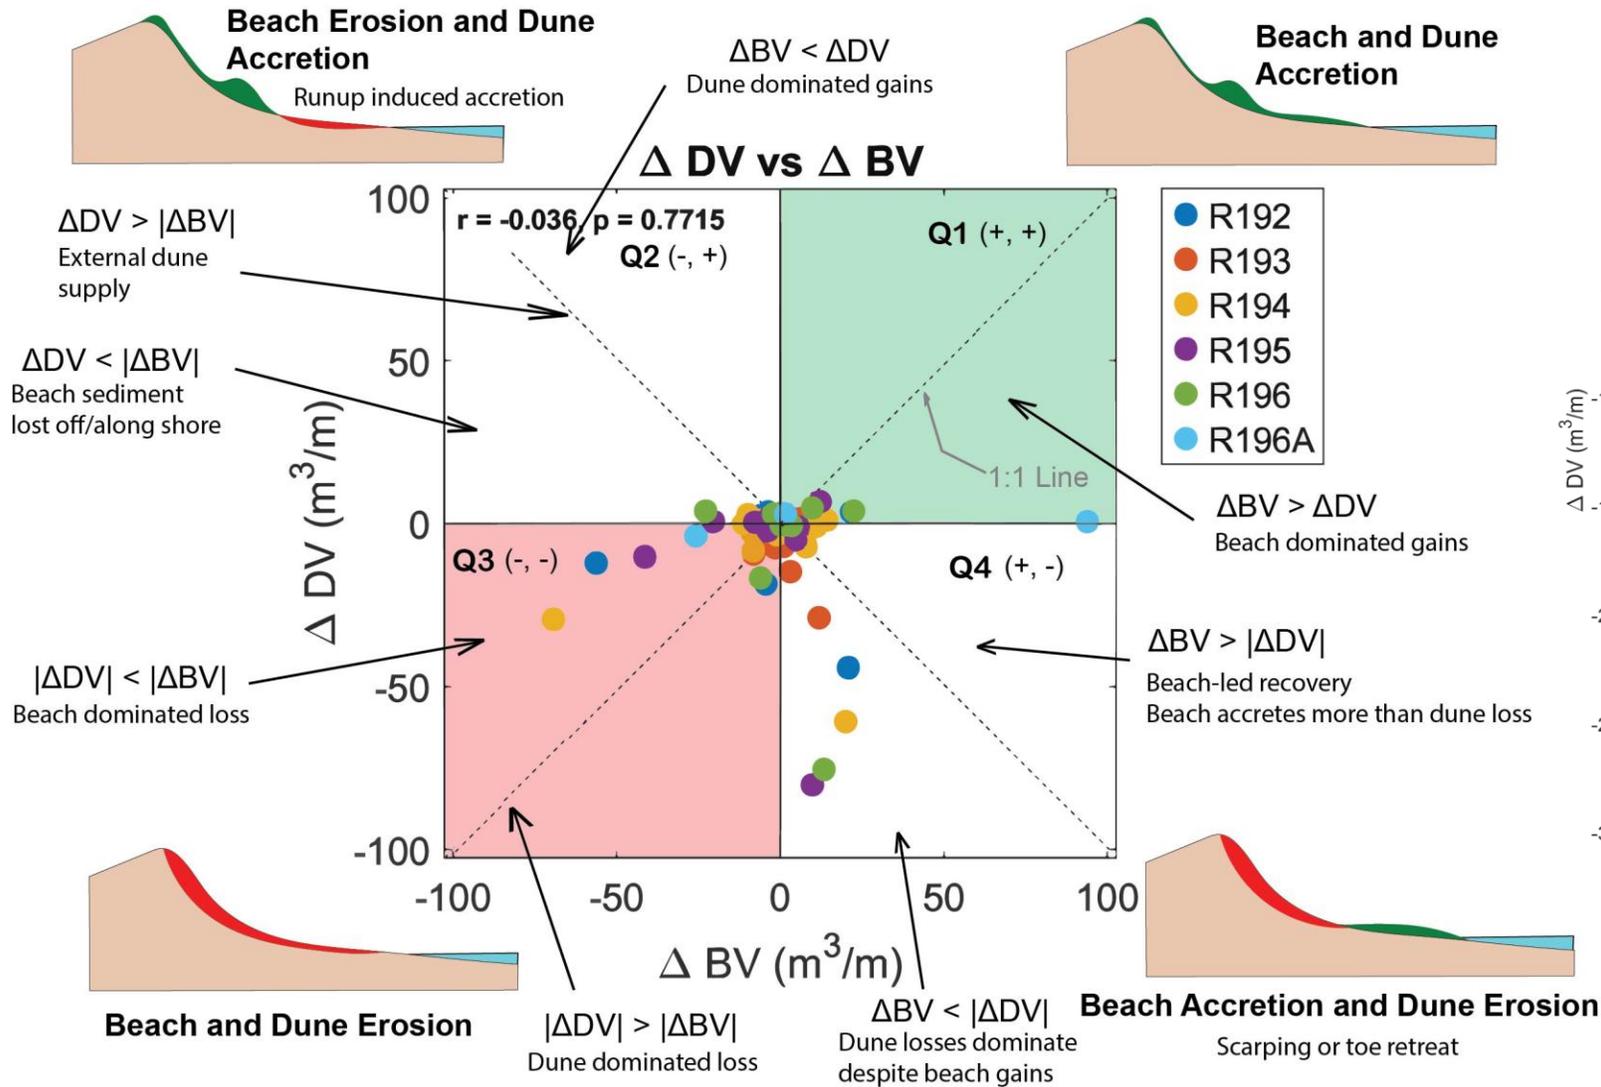

$$fD = \Delta Dv/S$$

$$fB = \Delta Bv/S$$

$$fN = \Delta Nv/S$$

Sequential Change

Points = volume change between consecutive surveys

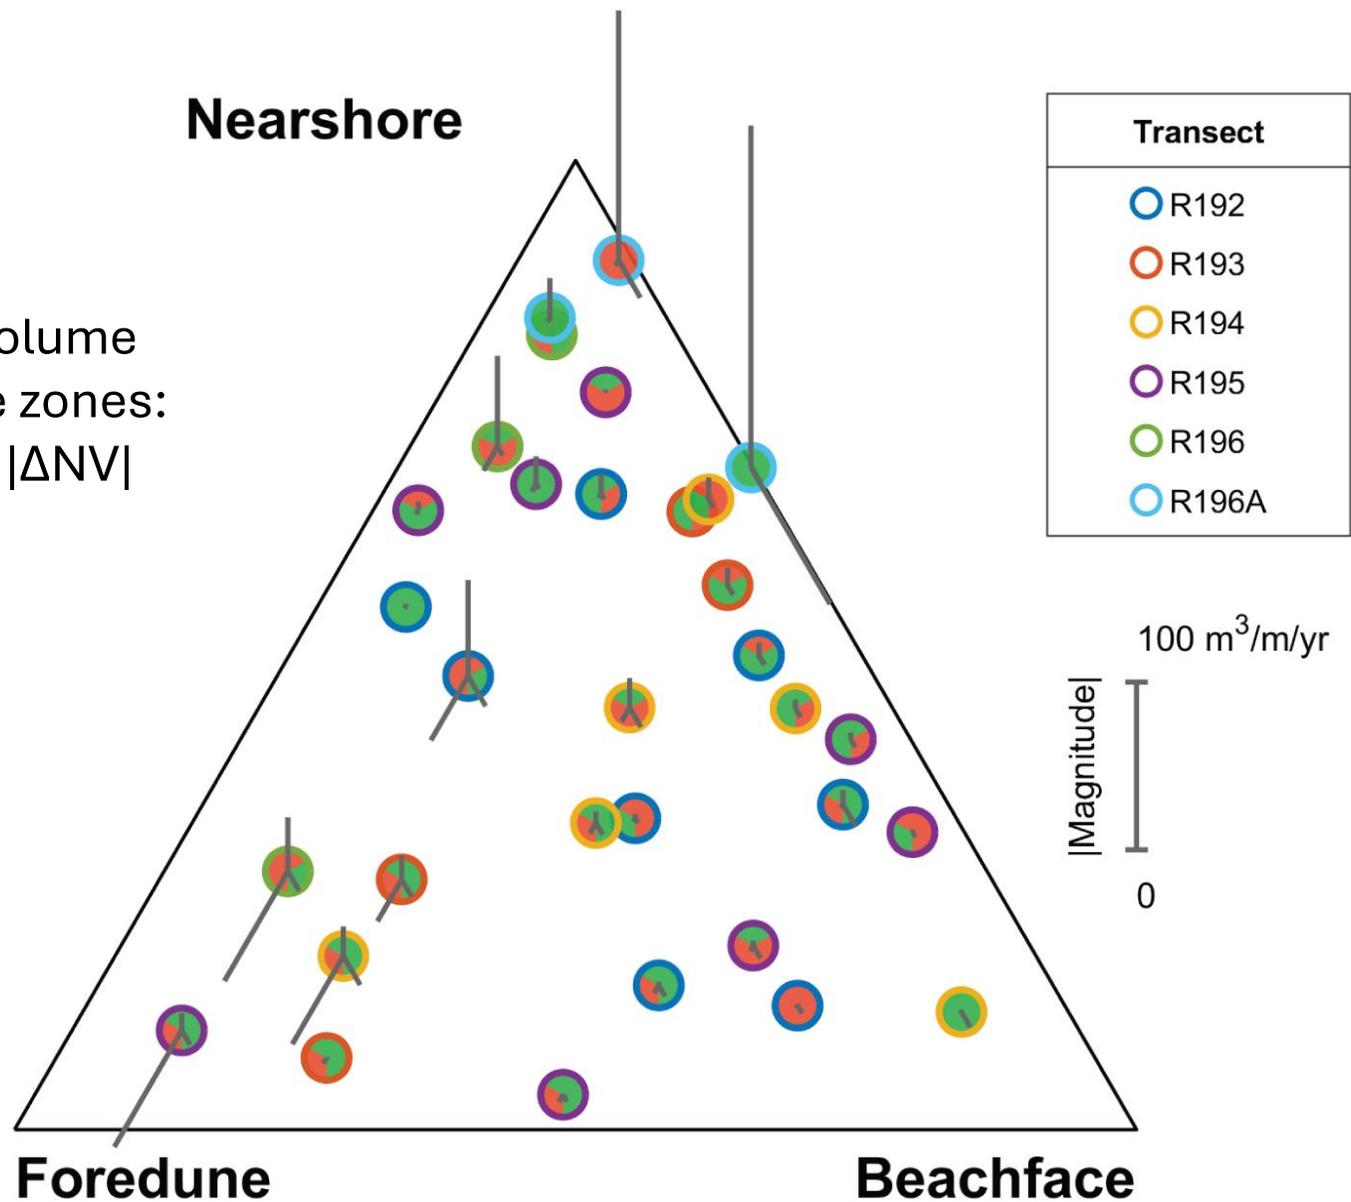

Fractions of total volume change among three zones:

$$S = |\Delta DV| + |\Delta BV| + |\Delta NV|$$

$$fD = \Delta Dv/S$$

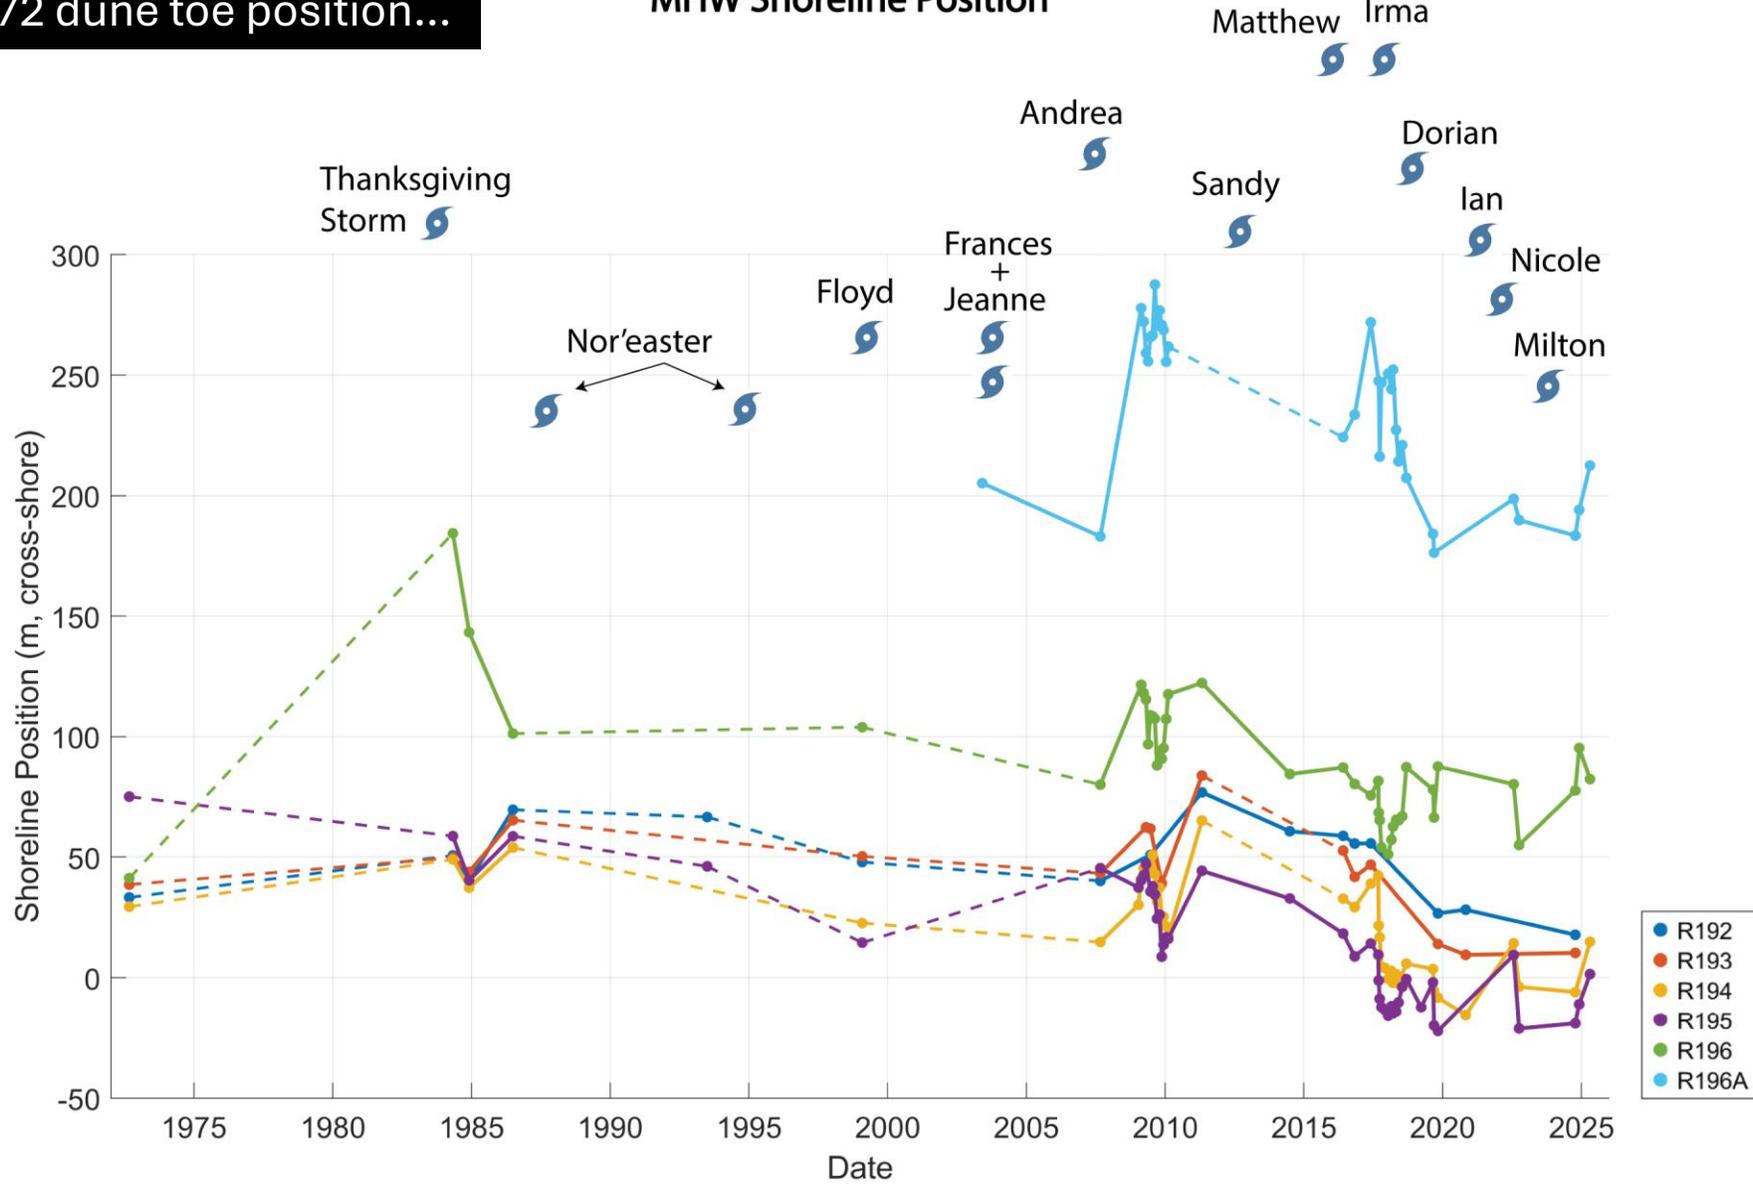

$$fB = \Delta Bv/S$$

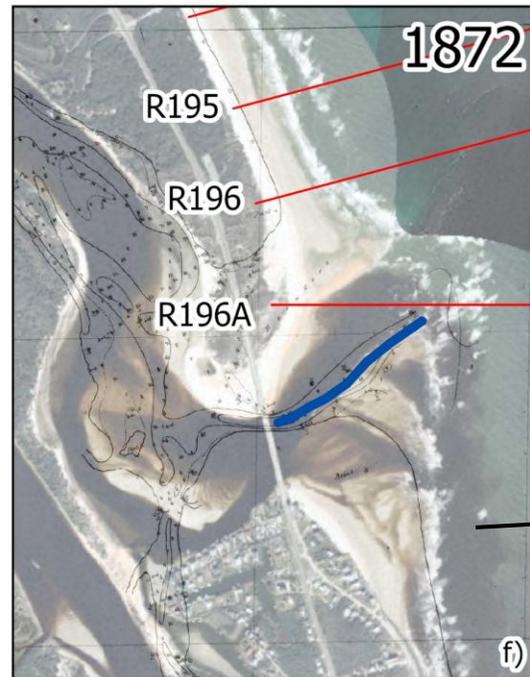

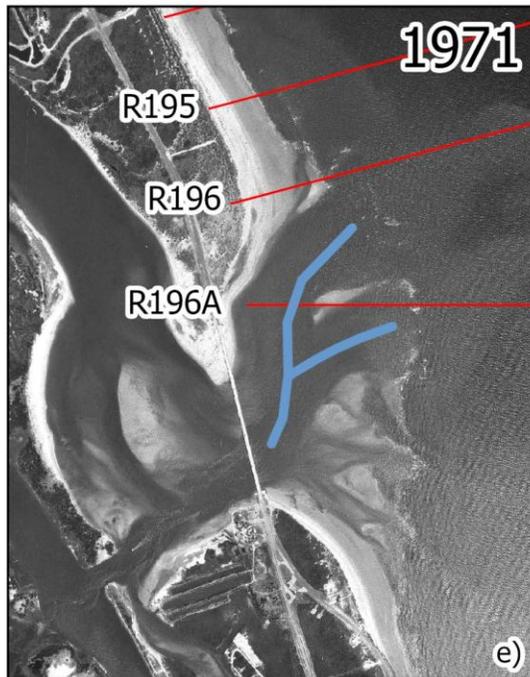

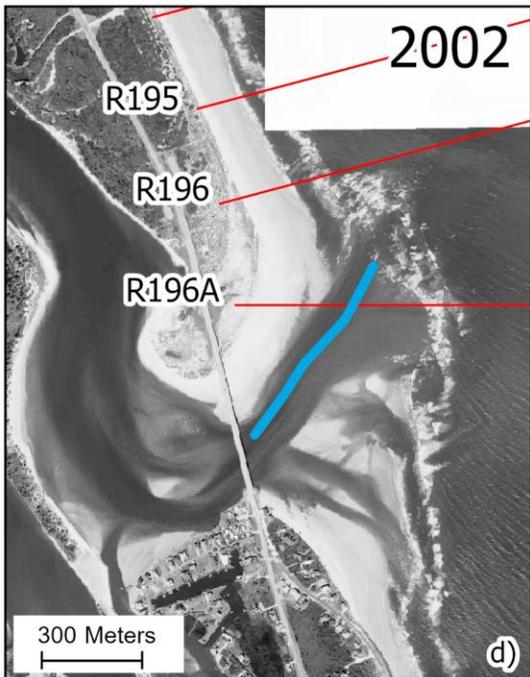

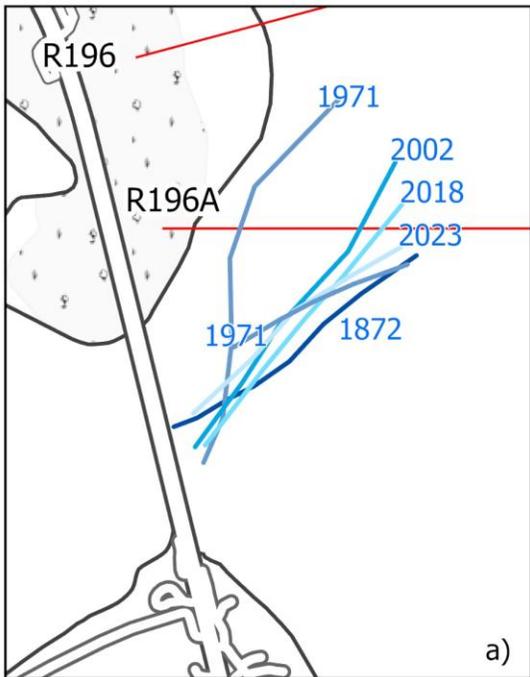

$$fN = \Delta Nv/S$$
